# **Events**

Mendel Rosenblum

# DOM communicates to JavaScript with Events

#### Event types:

- Mouse-related: mouse movement, button click, enter/leave element
- Keyboard-related: down, up, press
- Focus-related: focus in, focus out (blur)
- Input field changed, Form submitted
- Timer events
- Miscellaneous:
  - Content of an element has changed
  - Page loaded/unloaded
  - Image loaded
  - Uncaught exception

# **Event handling**

Creating an event handler: must specify 3 things:

- What happened: the event of interest.
- Where it happened: an element of interest.
- What to do: JavaScript to invoke when the event occurs on the element.

# Specifying the JavaScript of an Event

Option #1: in the HTML:

```
<div onclick="gotMouseClick('id42'); gotMouse=true;">...</div>
```

Option #2: from Javascript using the DOM:

```
element.onclick = mouseClick;
    or
element.addEventListener("click", mouseClick);
```

# Event object

- Event listener functions passed an Event object
   Typically sub-classed MouseEvent, KeyboardEvent, etc.
- Some Event properties:

```
type - The name of the event ('click', 'mouseDown', 'keyUp', ...)

timeStamp - The time that the event was created

currentTarget - Element that listener was registered on

target - Element that dispatched the event
```

#### MouseEvent and KeyboardEvent

Some MouseEvent properties (prototype inherits from Event)

button - mouse button that was pressed
pageX, pageY: mouse position relative to the top-left corner of document
screenX, screenY: mouse position in screen coordinates

Some KeyboardEvent properties (prototype inherits from Event)

keyCode: identifier for the keyboard key that was pressed Not necessarily an ASCII character!

charCode: integer Unicode value corresponding to keypress, if there is one.

# Draggable Rectangle - HTML/CSS

```
<style type="text/css">
  #div1 {
   position: absolute;
</style>
<div id="div1" onmousedown="mouseDown(event);"</pre>
   onmousemove="mouseMove(event);"
   onmouseup="mouseUp(event);">Drag Me!</div>
```

# Draggable Rectangle - JavaScript

```
var isMouseDown = false; // Dragging?
var prevX, prevY;
function mouseDown(event) {
   prevX = event.pageX;
   prevY = event.pageY;
   isMouseDown = true;
function mouseUp(event) {
  isMouseDown = false;
```

```
function mouseMove(event) {
   if (!isMouseDown) {
     return;
  var elem = document.getElementById("div1");
  elem.style.left = (elem.offsetLeft +
          (event.pageX - prevX)) + "px";
  elem.style.top = (elem.offsetTop +
          (event.pageY - prevY)) + "px";
   prevX = event.pageX;
   prevY = event.pageY;
```

# Deciding which handler(s) are invoked for an event?

Complicating factor: elements can contain or overlap other elements

Suppose user clicks with the mouse on "xyz" in:

```
<body>

xyz

</body>
```

If I have handlers on the td, tr, table, and body elements which get called?

- Sometimes only the innermost element should handle the event
- Sometimes it's more convenient for an outer element to handle the event

## Capturing and Bubbling Events

- Capture phase (or "trickle-down"):
  - Start at the outermost element and work down to the innermost nested element.
  - Each element can stop the capture, so that its children never see the event event.stopPropagation()

```
element.addEventListener(eventType, handler, true);
```

- Bubble phase Most on handlers (e.g. onclick) use bubble, not onfocus/blur
  - Invoke handlers on the innermost nested element that dispatches the event (mostly right thing)
  - Then repeat on its parent, grandparent, etc. Any given element can stop the bubbling:
     event.stopPropagation()

```
element.addEventListener(eventType, handler, false);
```

Handlers in the bubble phase more common than capture phase

#### **Example: Timer Events**

Run myfunc once, 5 seconds from now:

```
token = setTimeout(myFunc, 5*1000);
```

Function is called in specified number of milliseconds

Run myfunc every 50 milliseconds:

```
token = setInterval(myfunc, 50);
```

Cancel a timer:

```
clearInterval(token);
```

Used for animations, automatic page refreshes, etc.

## **Event Concurrency**

- Events are serialized and processed one-at-a-time
- Event handling does not interleave with other Javascript execution.
  - Handlers run to completion
  - No multi-threading.
- Make reasoning about concurrency easier
  - Rarely need locks.
- Background processing is harder than with threads

# Event-based programming is different

- Must wait for someone to invoke your code.
- Must return quickly from the handler (otherwise the application will lock up).
- Key is to maintain control through events: make sure you have declared enough handlers; last resort is a timer.
- Node.js uses event dispatching engine in JavaScript for server programming
